This document was copied as is from the Cocoon 2.1 documentation, but has not yet been fully reviewed or moved to its new home.

1. Concept

An fd:booleanfield is a field that has a value of true or false. Usually is rendered as a checkbox.

It is different from a [field widget](#) with a boolean datatype because an HTML checkbox submits no request parameter if the checkbox is unchecked. If you would render it instead as a listbox with true and false values, you could also use a regular field widget. Since the styling preference might change over time, it is however better to use consistently the fd:booleanfield widget.

A booleanfield cannot be marked as "required", because it is always required. It is either true or false. If you want tripples (true/false/none), use a normal field widget with a selection list.

2. Configuration

```
<fd:booleanfield id="..."> <fd:label>...</fd:label> <fd:help>...</fd:help> <fd:hint>...</fd:hint>  
<fd:on-value-changed> [...] </fd:on-value-changed> </fd:booleanfield>
```

See [field widget](#) for a description of the configuration options.
